what a damping excess $\delta\hat{\tau}_{220} = 0.14$ would need
0.444 at a/M = 0.9, a fifth of the energy returned
with the co−rotation term, as the formula has it
without it, as the bound assumed
10^{-6} at the same spin
the two agree only at zero spin, where the horizon is not rotating; away from it the term reverses the answer rather than shifting it.
